▪ Conclusion	19

INTRODUCTION:

In the modern retail environment, understanding customer purchasing behavior is essential for improving sales performance, enhancing customer satisfaction, and optimizing product strategies. Purchase Pattern Analytics enables organizations to analyze transactional data and identify relationships between products purchased together.

This project applies **Market Basket Analysis (MBA)** using **Python, SQL, and Power BI** to uncover hidden product associations, customer behavior patterns, and actionable business insights. The Apriori algorithm is used to identify frequent itemsets and association rules that support cross-selling and sales optimization strategies.

PROBLEM STATEMENT:

The objective of this project is to leverage Market Basket Analysis on retail transaction data to uncover relationships between products. By performing exploratory data analysis, addressing data quality issues, implementing visualization techniques, and applying the Apriori algorithm, the goal is to extract insights that improve sales strategies and customer satisfaction.

(Note: The SQL queries are mention in the colour – [SQL QUERIES](#))

It shows the available database as '[project_purchase_pattern_analysis](#)' and the table present within the database as '[mytable](#)'.

• Project Overview & Roadmap

SQL-Based Exploratory Data Analysis & Business Queries

Database Initialization and Data Review

The analysis begins by selecting the project database and reviewing the available tables. The transaction table is explored to understand its structure, column names, and data types. This step ensures familiarity with the dataset before performing analytical operations. A full table preview and schema description are performed to validate data completeness and field definitions.

`DESCRIBE mytable;`

It shows the available **fields, datatypes of the fields and also it shows whether there is null values present in the data** This query is used to examine the structure of the transaction. This query is used to examine the structure of the transaction table. It provides details about

```
1 •      use project_purchase_pattern_analysis;
2 •      show tables;
3 •      select * from mytable;
4 •      DESCRIBE mytable;|
5
```

The screenshot shows the MySQL Workbench interface with the 'result Grid' tab selected. The results of the DESCRIBE query are displayed in a table with the following columns: Field, Type, Null, Key, Default, and Extra. The table contains the following data:

Field	Type	Null	Key	Default	Extra
BillNo	varchar(7)	NO		NULL	
Itemname	varchar(36)	YES		NULL	
Quantity	int(11)	YES		NULL	
Present_Date	varchar(16)	YES		NULL	
Price	decimal(9,3)	YES		NULL	
CustomerID	varchar(255)	YES		NULL	
Country	varchar(20)	YES		NULL	

each column, including column names, data types, and whether null values are allowed.

Business Purpose:

Understanding the table schema ensures correct interpretation of fields such as transaction ID, product name, quantity, price, customer ID, and date before performing analysis.

Why it is Important:

- Validates data types for accurate calculations
- Helps identify columns that may contain missing values
- Supports effective data cleaning and preprocessing

STEP 1: EXPLORATORY DATA ANALYSIS (EDA)

Total Transactions

The total number of unique transactions is calculated using distinct bill numbers.

Purpose:

To understand overall transaction volume and customer purchase activity.

Business Value:

This metric represents how many purchase events occurred and serves as a base KPI for sales analysis.

```
SELECT COUNT(DISTINCT BillNo) AS total_transactions  
FROM mytable;
```

A screenshot of a database query results grid. The query is:

```
68 -- 1.Total Transactions  
69 • SELECT COUNT(DISTINCT BillNo) AS total_transactions  
70   FROM mytable;
```

The results grid shows one row with the following data:

total_transactions
21663

Total Products

The total number of unique products is calculated using distinct item names.

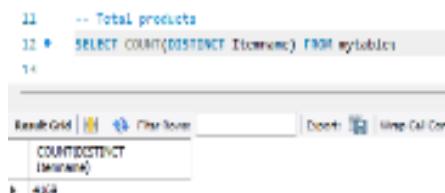

Purpose:

To identify product diversity within the dataset.

Business Value:

Helps assess inventory breadth and product variety offered to customers.

```
SELECT DISTINCT Routes FROM supply_chain_table;
```

A screenshot of a database query results grid. The query is:

```
11 -- Total products  
12 • SELECT COUNT(DISTINCT ItemName) FROM mytable  
13  
14
```

The results grid shows one row with the following data:

COUNT(DISTINCT ItemName)
4368

Average Basket Size

The average number of distinct products per transaction is calculate

```
SELECT AVG(item_count) FROM  
(SELECT BillNo, COUNT(DISTINCT Itemname) AS item_count  
FROM mytable  
GROUP BY BillNo  
) t;
```

```
14    -- Average basket size  
15 •  SELECT AVG(item_count)  
16   FROM (  
17     SELECT BillNo, COUNT(DISTINCT Itemname) AS item_count  
18     FROM mytable  
19     GROUP BY BillNo  
20   ) t;  
21
```

The screenshot shows a database query results grid. At the top, there are buttons for 'Result Grid', 'Filter Rows', 'Export', and 'Wrap Cell Content'. Below the buttons, the query text is displayed. The result grid has one row with two columns: 'AVG(item_count)' and '23.6015'.

AVG(item_count)	23.6015

DATA QUALITY VALIDATION AND CLEANING

Before performing business analysis, data quality checks are conducted to ensure accuracy.

Missing Value Check

Null values are identified across critical columns such as Bill Number, Item Name, Quantity, Price, and Customer ID.

```
SELECT  
SUM(BillNo IS NULL) AS null_billno,  
SUM(Itemname IS NULL) AS null_itemname,  
SUM(Quantity IS NULL) AS null_quantity,  
SUM(Price IS NULL) AS null_price,  
SUM(CustomerID IS NULL) AS null_customer  
FROM mytable;
```

```
1  
2  -- Data Quality Validation And Cleaning  
3  
4  -- Handle Missing Values (NULL CHECK)  
5 •  SELECT  
6    SUM(BillNo IS NULL) AS null_billno,  
7    SUM(Itemname IS NULL) AS null_itemname,  
8    SUM(Quantity IS NULL) AS null_quantity,  
9    SUM(Price IS NULL) AS null_price,  
10   SUM(CustomerID IS NULL) AS null_customer  
11  FROM mytable;  
12
```

The screenshot shows a database query results grid. At the top, there are buttons for 'Result Grid', 'Filter Rows', 'Export', and 'Wrap Cell Content'. Below the buttons, the query text is displayed. The result grid has five columns: 'null_billno', 'null_itemname', 'null_quantity', 'null_price', and 'null_customer'. All columns have a value of 0.

null_billno	null_itemname	null_quantity	null_price	null_customer
0	0	0	0	0

- **Cancelled Transaction Removal**

Cancelled invoices (identified by bill numbers starting with “C”) are excluded.

Purpose:

To remove non-sales transactions from analysis.

Business Value:

Ensures revenue and basket metrics reflect only completed purchases.

`SELECT * FROM mytable`

`WHERE BillNo NOT LIKE 'C%'; distinct;`

The screenshot shows a code editor with a SQL query and a data grid. The code is as follows:

```
46 -- Remove Cancelled Transactions (Retail Rule)
47 • SELECT *
48 FROM mytable
49 WHERE BillNo NOT LIKE 'C%'
50
```

The data grid below the code shows transaction details:

BillNo	ItemName	Quantity	Present_Date	Price	CustomerID	Country
536355	WHITE HANGING HEART LIGHT HOLDER	6	01-12-2010 08:26	3.550	17850	United Kingdom
536355	WHITE METAL LANTERN	6	01-12-2010 08:26	3.390	17850	United Kingdom
536355	CROWN CLIPED HEARTS COAT HANGER	8	01-12-2010 08:26	3.750	17850	United Kingdom
536355	KNOTTED UNION FLAG HOT WATER BOTTLE	6	01-12-2010 08:26	3.390	17850	United Kingdom

- **Date Cleaning**

Transaction dates stored as text are converted into proper date format.

Purpose

To enable time-based analysis.

Business Value:

Allows accurate daily, monthly, and trend-based reporting.

`SELECT`

`STR_TO_DATE(Present_Date, '%d-%m-%Y %H:%i') AS`

`clean_date`

`FROM mytable;`

```

52    -- Date Cleaning (Text to Date)
53 *  SELECT
54      STR_TO_DATE(Present_Date, '%d-%m-%Y %H:%i') AS clean_date
55  FROM mytable;
56

```

The screenshot shows a database query editor with the following code:

```

52    -- Date Cleaning (Text to Date)
53 *  SELECT
54      STR_TO_DATE(Present_Date, '%d-%m-%Y %H:%i') AS clean_date
55  FROM mytable;
56

```

Below the code is a result grid titled "Result Grid". It has a single column named "clean_date" containing 20 rows of data, all showing the same value: 2010-12-01 08:26:00.

- **Final Clean Dataset Creation:**

final cleaned dataset is created by filtering:

- Positive quantity
- Positive price
- Non-null item names
- Non-cancelled transactions

- **Purpose:**

To create a trusted analytical dataset.

- **Business Value:**

Forms a reliable foundation for Power BI dashboards and Python analysis.

```

SELECT DISTINCT
BillNo,
Itemname
FROM mytable
WHERE Quantity > 0
AND Price > 0
AND Itemname IS NOT NULL
AND BillNo NOT LIKE 'C%';

```

```

57    -- FINAL CLEAN DATASET
58 •  SELECT DISTINCT
59      BillNo,
60      Itemname
61  FROM mytable
62 WHERE Quantity > 0
63   AND Price > 0
64   AND Itemname IS NOT NULL
65   AND BillNo NOT LIKE 'C%';

```

STEP 2: BUSINESS QUERIES & KEY METRICS

Total Transactions

The final transaction count is recalculated from the clean dataset.

Business Meaning:

Represents actual sales events after data cleansing.

```
SELECT COUNT(DISTINCT BillNo) AS total_transactions  
FROM mytable;
```

```
68    -- 1.Total Transactions  
69 •  SELECT COUNT(DISTINCT BillNo) AS total_transactions  
70    FROM mytable;  
  
Result Grid | Filter Rows: _____ | Export: _____ | Wrap Cell Content: _____  
total_transactions  
21663
```

Average Basket Size

The average number of items per transaction is recalculated using only valid records.

Business Meaning:

Indicates customer purchasing depth and cross-sell potential.

```
SELECT AVG(item_count)  
FROM (  
    SELECT BillNo, COUNT(DISTINCT Itemname) AS item_count  
    FROM mytable  
    GROUP BY BillNo  
) t;
```

```
72    -- 2.Average Basket Size  
73 •  SELECT AVG(item_count)  
74    FROM (  
75        SELECT BillNo, COUNT(DISTINCT Itemname) AS item_count  
76        FROM mytable  
77        GROUP BY BillNo  
78    ) t;  
  
Result Grid | Filter Rows: _____ | Export: _____ | Wrap Cell Content: _____  
total_transactions  
21663
```

Total Revenue

Total revenue is calculated as the sum of quantity multiplied by price.

Business Meaning:

Represents total business sales value.

```

SELECT
SUM(Quantity * Price) AS total_revenue
FROM mytable
WHERE Quantity > 0 AND Price > 0;

```

```

80      -- 3.Total Revenue
81 •   SELECT
82     SUM(Quantity * Price) AS total_revenue
83   FROM mytable
84   WHERE Quantity > 0 AND Price > 0;
85

```

total_revenue
10301894.974

Daily Sales Trend

Revenue is aggregated by transaction date.

Business Meaning:

Helps identify sales patterns, peak days, and demand fluctuations.

```
SELECT
```

```

DATE(STR_TO_DATE(Present_Date, '%d-%m-%Y %H:%i')) AS sales_date,
SUM(Quantity * Price) AS daily_revenue
FROM mytable
GROUP BY sales_date;

```

```

123      -- 8.Daily Revenue Trend
124 •   SELECT
125     DATE(STR_TO_DATE(Present_Date, '%d-%m-%Y %H:%i')) AS sales_date,
126     SUM(Quantity * Price) AS daily_revenue
127   FROM mytable
128   WHERE Quantity > 0
129     AND Price > 0
130   GROUP BY sales_date
131   ORDER BY sales_date;
132
133

```

sales_date	daily_revenue
2010-12-01	58405.410
2010-12-02	47725.880
2010-12-03	44366.860
2010-12-05	31774.950
2010-12-06	53647.960

2010-12-17	43994.210
2010-12-19	7123.810
2010-12-20	26789.130

Top 10 Best-Selling Products

Products are ranked based on purchase frequency.

Business Meaning:

Identifies high-demand products and supports inventory and promotion decisions.

```
SELECT Itemname,  
       COUNT(*) AS purchase_count  
  FROM mytable  
 GROUP BY Itemname  
 ORDER BY purchase_count DESC  
 LIMIT 5;
```

The screenshot shows a database query results grid. At the top, there is a code block with numbered lines 93 through 99. Lines 94-99 contain the SQL query. Below the code is a results grid with two columns: 'Itemname' and 'purchase_count'. The data rows are: WHITE HANGING HEART T-LIGHT HOLDER (2269), JUMBO BAG RED RETROSPOT (2087), REGENCY CAKESTAND 3 TIER (1930), PARTY BUNTING (1677), and LUNCH BAG RED RETROSPOT (1570). The grid has a header row and five data rows. There are buttons for 'Result Grid', 'Filter Rows', 'Export', and 'Wrap Cell Content'.

Itemname	purchase_count
WHITE HANGING HEART T-LIGHT HOLDER	2269
JUMBO BAG RED RETROSPOT	2087
REGENCY CAKESTAND 3 TIER	1930
PARTY BUNTING	1677
LUNCH BAG RED RETROSPOT	1570

Revenue by Country:

Revenue contribution is analyzed at the country level.

Business Meaning:

Provides geographic insights for regional performance and market analysis.

```
SELECT Country , SUM(Quantity * Price) AS country_revenue  
  FROM mytable  
 WHERE Quantity > 0  
   AND Price > 0  
 GROUP BY Country  
 ORDER BY country_revenue DESC;
```

```

114  -- 7.Revenue by Country
115  •   SELECT
116      Country,
117      SUM(Quantity * Price) AS country_revenue
118  FROM mytable
119  WHERE Quantity > 0
120  AND Price > 0
121  GROUP BY Country
122  ORDER BY country_revenue DESC;
123

```

Python Analysis & Apriori Algorithm Implementation

After completing SQL-based exploratory analysis and data cleaning, Python was used to perform Market Basket Analysis using the Apriori algorithm. This phase focused on preparing transaction data, identifying product co-occurrence patterns, and generating inputs for association rule mining.

Data Loading and Initial Inspection

The cleaned transaction dataset was loaded into Python using Pandas. Initial inspection was performed to validate the dataset structure, column names, and data types.

Data Type Validation and Column Standardization

Column names were standardized to improve clarity and consistency. Invoice numbers were converted to string format to support transaction-level grouping. Quantity fields were validated to ensure numerical consistency. This ensured uniform data representation across the dataset and avoided issues during aggregation and transformation.

Data Cleaning and Filtering

To maintain analytical accuracy, the following data cleaning steps were applied:

- Records with missing invoice numbers or product descriptions were removed
 - Cancelled transactions were excluded
 - Only transactions with positive quantity values were retained
- These steps ensured that only valid and completed sales transactions were included in the analysis.

One-Hot Encoding of Transactions

The transaction baskets were converted into a binary (one-hot encoded) matrix, where:

- Rows represent individual transactions
 - Columns represent products
 - Values indicate whether a product was purchased in a transaction
- This transformation is a mandatory input requirement for the Apriori algorithm.

Product Frequency Filtering

Product frequency was analyzed to identify commonly purchased items. Products with very low purchase frequency were removed to reduce noise and computational complexity. Only products purchased at least a minimum threshold number of times were retained. This resulted in a reduced and optimized dataset while preserving meaningful purchasing patterns.

After completing SQL-based exploratory analysis and data cleaning, Python was used to perform advanced analytical processing and Market Basket Analysis. The primary objective of this phase was to identify relationships between products purchased together and uncover hidden purchase patterns that cannot be identified using simple descriptive

Purpose of Python Analysis

Python was chosen for this phase due to its strong support for data manipulation and machine learning algorithms. It enables efficient transformation of transaction data into a format suitable for Market Basket Analysis and supports the implementation of the Apriori algorithm.

The Python analysis focused on:

- Preparing transaction-level data for association analysis
- Identifying frequently purchased product combinations
- Generating association rules for cross-selling insights

Data Preparation for Apriori

Before applying the Apriori algorithm, the cleaned transaction dataset was transformed into a basket format. Each transaction was represented as a collection of products purchased together. The data was then converted into a binary matrix, where each row represents a transaction and each column represents a product.

This transformation ensured that the dataset met the input requirements of the Apriori algorithm.

Apriori Algorithm Implementation

The Apriori algorithm was applied to identify frequent itemsets based on product co-occurrence within transactions. The algorithm uses support as a key metric to determine how frequently a product combination appears across all transactions.

After identifying frequent itemsets, association rules were generated using confidence and lift metrics:

- Support measures how often a product combination occurs
- Confidence indicates the likelihood of purchasing one product given another
- Lift evaluates the strength of the association beyond random chance

Output of Apriori Analysis

The Apriori analysis produced:

- A list of frequent itemsets representing commonly purchased product combinations
- Association rules highlighting strong relationships between products

These outputs provide clear insights into customer buying behavior and product affinities.

Business Value of Apriori Insights

The results of the Apriori analysis support several business use cases:

- Identification of product bundling opportunities
- Improved cross-selling and upselling strategies

- **IMPORTING DATA IN POWERBI:**

After completing SQL-based exploratory analysis and Python-based Market Basket Analysis, Power BI was used to visualize key insights and present business findings in an interactive and user-friendly format. The objective of the Power BI dashboard is to enable stakeholders to quickly understand sales performance, customer behavior, product contribution, and geographic trends.

Purpose of Using Power BI

Power BI was selected as the visualization tool due to its ability to:

- Present complex data insights in an intuitive manner
 - Enable interactive filtering and drill-down analysis
 - Support data-driven decision-making for business users
- The dashboard acts as a decision-support system rather than a technical report.

Data Source for Power BI

The Power BI dashboard was built using the cleaned transaction dataset, which was prepared through:

- SQL-based data validation and cleaning
 - Python-based preprocessing for advanced analysis
- Only valid and completed transactions were used to ensure accuracy and reliability.

DAX MEASURES:

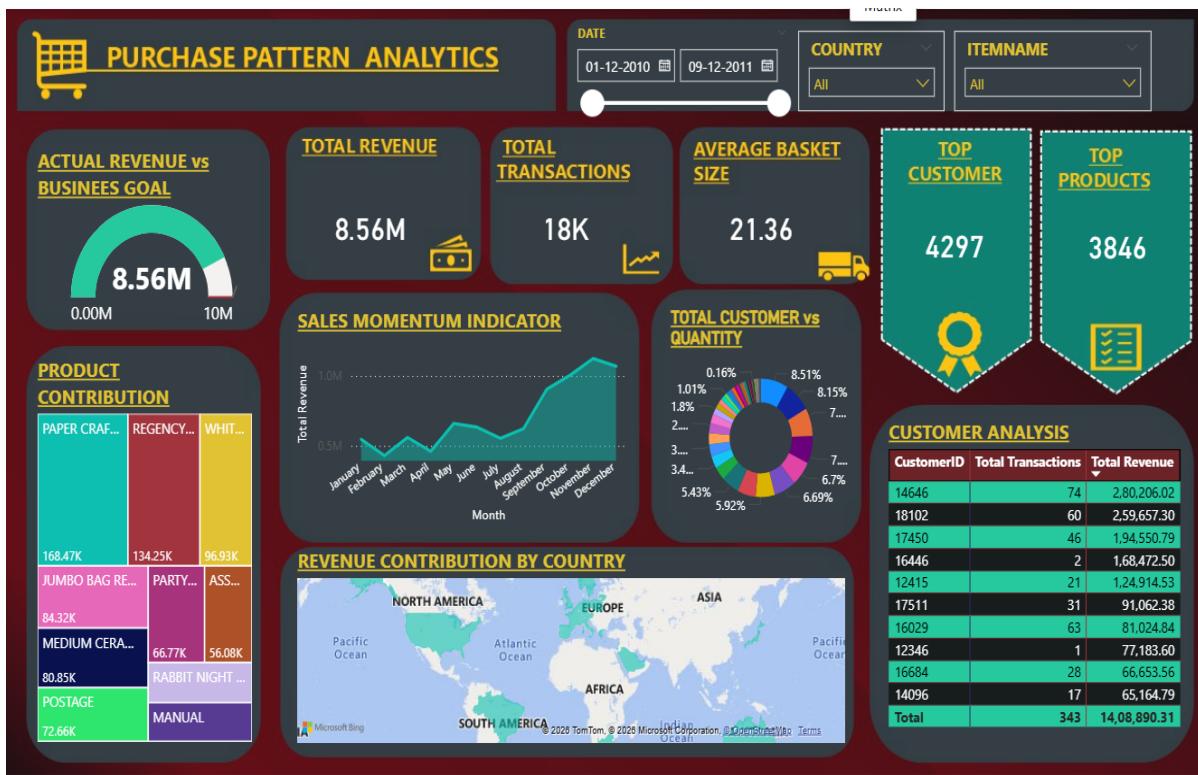

DAX is called as DATA ANALYSIS EXPRESSIONS and it is used for data analysis and calculations after the data has been loaded into Power BI or Excel. It is used to create measures, calculated columns, and perform complex aggregations.

Exploring New Columns with DAX Measures

To support the insights shown in the dashboard, additional DAX measures were created to calculate key business metrics such as **Total Revenue, Total Transactions, Average Basket Size, Product Contribution, and Customer Performance**.

These measures enable real-time calculations across filters and slicers, ensuring that KPIs, sales trends, product-wise analysis, customer insights, and country-level revenue update dynamically. The use of DAX ensures accuracy, consistency, and clarity in presenting business performance through the dashboard visuals.

- **DASHBOARD**

Dashboard Consists of:

- Displays overall sales performance using **Total Revenue**, **Total Transactions**, and **Average Basket Size**
- Compares **Actual Revenue vs Business Goal** to track target achievement
- Shows **monthly sales trends** using the Sales Momentum Indicator
- Highlights **top-performing products** through Product Contribution treemap
- Identifies **Top Customers** and **Top Products** for focused business strategies
- Analyzes **customer purchase quantity distribution** using donut chart
- Visualizes **country-wise revenue contribution** through interactive map
- Provides **Customer Analysis table** to identify high-value customers
- Includes **Date, Country, and Item Name slicers** for interactive analysis
- Supports data-driven decisions for **sales, marketing, and customer retention**

Insights & Business Recommendations

Key Insights

- Customer purchasing behavior indicates a strong tendency toward multi-item transactions, highlighting opportunities for cross-selling.
- Sales performance demonstrates identifiable trends over time, supporting demand forecasting and planning.
- Revenue is distributed across a broad range of products, indicating a balanced and low-risk product portfolio.
- A segment of repeat customers contributes a significant share of transactions and revenue.
- Market Basket Analysis reveals consistent product pairings, confirming meaningful purchase relationships.
- Geographic analysis highlights both high-performing regions and markets with growth potential.

Business Recommendations

- Introduce bundled offers and promotions based on frequently purchased product combinations.
- Apply targeted cross-sell strategies to increase average basket size and transaction value.
- Align marketing and promotional activities with peak sales periods to maximize impact.
- Develop loyalty programs to retain high-value and repeat customers.
- Use product contribution insights to optimize inventory planning and shelf placement.
- Focus expansion and targeted campaigns on underperforming regions to drive balanced growth.

CONCLUSION:

- Successfully analyzed retail transaction data to understand customer purchasing behavior and sales patterns.
- Ensured data accuracy and reliability through structured exploratory analysis and validation.
- Identified meaningful product associations using Python-based Market Basket Analysis (Apriori).
- Delivered an interactive Power BI dashboard to visualize revenue, transactions, basket size, products, customers, and geography.
- Enabled data-driven decision-making for cross-selling, product bundling, customer targeting, and regional growth.
